ABSTRACT

Medicinal plants have been identified and used as primary sources in prevention and treatment of pulmonary diseases (mainly obstructive pulmonary diseases) from ancient times due to various pharmacological activities. In this review, the stimulatory effects of extracts, some fractions and constituents of medicinal plants on $\beta_2$-adrenoceptors which could be used as possible therapeutic agents in the future were reviewed.

Various databases including Medline, PubMed, ScienceDirect, Scopus, and Google Scholar were searched using stimulatory effect, $\beta_2$-adrenoceptors, possible mechanism, tracheal smooth muscle (TSM), medicinal plants and their constituents as keywords from 1985 to 2017.

All studied plants including; Nigella sativa, Rosa damascena, Thymus vulgaris, Carum copticom, Carum carvi, Zataria multiflora, Crocus sativus, Cuminum cyminum, Lionnnia acidissima, Portulaca oleracea, Satureja hortensis, Ephedra sinica and Achillea millefolium showed relaxant effect on tracheal smooth muscle with a stimulatory effect on $\beta_2$-adrenoceptors mechanism.

The studied plants and their constituents could be of therapeutic value in clinical practice as a bronchodilatory drug by $\beta_2$-adrenoceptors stimulatory mechanism for treatment of obstructive pulmonary diseases.

Keywords: $\beta_2$-adrenoceptors; Medicinal plant; Possible mechanism; Stimulatory effect; Tracheal smooth muscle

INTRODUCTION

Obstructive lung disease, including asthma,\textsuperscript{1} bronchiectasis, bronchitis\textsuperscript{2} and chronic obstructive pulmonary disease (COPD)\textsuperscript{3} have been specified by thickening of the airway walls, infiltration of inflammatory cells\textsuperscript{4,5}, enhanced smooth muscle mass\textsuperscript{6} and mucus secretion, epithelial shedding.\textsuperscript{7,8}
The Stimulatory Effects of Medicinal Plants on β2-adrenoceptors

hypertrophy and hyperplasia of airway smooth muscle, and inflammation of the airways. Common medications in asthma treatment include bronchodilators and anti-inflammatory drugs. Quick-relief medicines or bronchodilators include short-acting inhaled β2-agonists and anticholinergic, while long-term control medicines or anti-inflammatory drugs consist of antileukotrienes, cromolyn sodium, inhaled corticosteroids, long-acting inhaled β2-agonists, methylxanthines, and oral corticosteroids.

Bronchodilators are a type of remedy used to treat asthma and COPD by dilation the bronchi and bronchioles, reducing resistance of the airways and enhancing airflow to the lungs. Bronchodilators may be endogenous that arise naturally within the body; nitric oxide (NO) is the endogenous neurotransmitter of bronchodilator nerves that produced in different parts of the body, including endothelial and epithelial cells, nerves, airway smooth muscle, and inflammatory cells.

The most important type of bronchodilator medications that applied for reliving treatment of obstructive pulmonary disease is β2-agonists that stimulated β2-adrenoceptors in tracheal smooth muscles (TSM). β adrenergic receptors are a member of the seven trans membrane family of receptors. Following β2-adrenoceptor activation, second messenger cyclic adenosine monophosphate (cAMP) produced in the lung, which lead to decrease in calcium concentrations within cells, activate protein kinase A and myosin light-chain phosphatase, inactivate myosin light-chain kinase, open large conductance calcium-activated potassium channels and therefore produce smooth muscle relaxation and bronchodilation (Figure 1).

Herbal medicines are the major source of health care for the world’s population. Plants have a wide variety of secondary metabolites, such as flavonoids, alkaloids, trepenoids and coumarins, which have therapeutic properties. In the recent years, interest in drugs of plant origin has been progressively increased. In developing countries 80% of the population relies mainly on herbal medicine in primary medical problems.

The relaxant effect of different medicinal plants such as Rosmarinus officinalis, Hydrastis Canadensis, Ferula assa-foetida, Foeniculum vulgare, Sarcoco ccaalina, Pimpinella anisum, Achillea wilhelmsii and Syzygium cumini on tracheal smooth muscle has been shown. The possible mechanisms have been suggested for the relaxant effects of medicinal plants on tracheal smooth muscles, including stimulation of β2-adrenergic receptors, inhibition of histamine (H1) receptors, calcium channel-blocking effect, potassium channel-opening effect, inhibitory effect on muscarinic receptors and methylxanthine activity.

Different studies showed β2-adrenoceptors stimulatory effect of various medicinal plants as the main mechanism of their tracheal smooth muscle relaxant effect. In this review, the stimulatory effects of the extracts, some fractions and constituents of the medicinal plants on β2-adrenoceptors on tracheal smooth muscle were reviewed.

MATERIALS AND METHODS

Online literature searches were performed using Medline, PubMed, ScienceDirect, Scopus, and Google Scholar websites from 1985 to 2017 to identify studies about the effects of medicinal plants on β2-adrenoceptors. The keywords used for searching were; medicinal plant, herbal medicine, β2-adrenoceptors receptors, relaxant effect, tracheal smooth muscle, β2-adrenoceptor competitive antagonists, propranolol, β2-adrenoceptor agonists, isoprenaline and possible mechanism. A total of 55 articles were identified by two authors separately, the search results were checked and 41 eligible articles were included in this review. Abstracts or unpublished articles and non-English language articles were excluded from study.

Methods for Examining β2-Adrenoceptor Stimulatory Effect of Medicinal Plants

The stimulatory effects of medicinal plant on β2-adrenoceptors are usually examined by three general methods.

1) Examining the relaxant effects of medicinal plants, their fractions and constituents in non-incubated and incubated tracheal smooth muscle with a pharmacological β2-competitive antagonist such as propranolol. In this method, reduced relaxant response in incubated tissues with β2-competitive antagonist will indicate a possible β2-adrenoceptor stimulatory effect. In some studies using this method, the effect of only one concentration of the extracts, fractions or constituents was examined. However, in other studies, the effect of the few concentrations were evaluated,
which the effective concentration inducing 50% of maximum response (EC_{50}) was also determined (Figure 2).

2) Performing concentration-response curve to histamine or methacholine in the presence and absence of the extracts, fractions or constituents of medicinal plants in non-incubated and incubated tracheal smooth muscle with a pharmacological β_{2}-adrenoceptors antagonist such as propranolol. The increased maximum response and EC_{50} as well as parallel shift in the concentration-response curve in the incubated tissues with pharmacological β_{2}-adrenoceptors antagonist will suggest a β_{2}-adrenoceptors stimulatory effect (Figure 3).

3) Performing concentration-response curve to a pharmacological β_{2}-adrenoceptors agonist such as isoprenaline in the present and the absence of the extracts of medicinal plants and their fractions or constituents. In this method, the shift of cumulative concentration-response curves to the left and reducing EC_{50} isoprenaline in the presence of the extracts, fractions or constituents will show their stimulatory effect on β_{2}-adrenoceptors. In this method, repeating concentration-response curve to a β_{2}-agonist in the presence of a β_{2}-competitive antagonist will increase the clarity which will shift the agonist response curve to the right (Figure 4). This method is the most precise pharmacological method for evaluation of the stimulatory effect of an agent on β_{2}-adrenoceptors.

**RESULTS**

**Effects of medicinal plants on β_{2}-adrenoceptors of tracheal smooth muscles by a competitive β_{2}-antagonist**

The possible stimulatory effect of various extracts, fractions and constituents of several medicinal plants were examined by assessment of their relaxant effect on non-incubated and incubated tissues with a pharmacological β_{2}-adrenoceptors competitive antagonist. The relaxant effects of hydro-alcoholic extract of *Achillea wilhelmsii* were examined by their relaxant effects on pre-contracted tracheal chains of guinea pig by KCl or methacholine, under two different conditions, non-incubated and incubated tissues with propranolol. There was no significant difference in the relaxant effect between non-incubated and incubated tissues contracted by methacholine. The results showed a potent relaxant effect of the extract from *Achillea wilhelmsii* on tracheal chains which was not due to the stimulatory effect of β_{2}-adrenergic receptors.\(^\text{35}\)

![Figure 1. Schematic representation of the sites of phosphorylation for protein kinase A (PKA). The combined effect of phosphorylation at these sites leads to tracheal smooth muscle relaxation. The Stimulatory Effects of Medicinal Plants on β2-adrenoceptors

Figure 2. Evaluation of the stimulatory effect of medicinal plants on β2-adrenoceptors by examining the relaxant effect of an agent on tracheal smooth muscle in non-incubated and incubated tissues with a β2-adrenoceptors competitive antagonist such as propranolol (a). A reduction in the relaxant effect in incubated tissue with β2-adrenoceptors competitive antagonist will suggest a β2-adrenoceptors stimulatory effect (a). In some studies, the effect of only one concentration of the agent is evaluated by this method (a). However, in other studies, the effect of few concentrations of the studied agent have been studied (b and c), and the concentration relaxant effect of the agent was performed (c) and EC50 is calculated (c).

Figure 3. Examining the stimulatory effect of medicinal plants on β2-adrenoceptors by performing concentration-response curve to histamine or methacholine in the presence and absence of the extracts, fractions or constituents of medicinal plants in non-incubated (a) and incubated (b) tracheal smooth muscles with a pharmacological β2-adrenoceptors antagonist such as propranolol. The increased maximum response and EC50 as well as parallel shift in the concentration-response curve in the incubated tissues with pharmacological β2-adrenoceptors antagonist (b) will suggest a β2-adrenoceptors stimulatory effect.
Figure 4. Examining the stimulatory effect of medicinal plants on β₂-adrenoceptors by performing concentration-response curve to a pharmacological β₂-adrenoceptors agonist such as isoprenaline in the present and the absence of the extracts of medicinal plants and their fractions or constituents. In this method, the shift of cumulative concentration-response curves to the left and reducing EC₅₀ agonist in the presence of the extracts, fractions or constituents will show their stimulatory effect on β₂-adrenoceptors. In addition, repeating concentration-response curve to a β₂-agonist in the presence of a β₂-competitive antagonist will increase the clarity, which will shift the agonist response curve to the right.

The relaxant effects of four fractions of essential oil from Carum copticum were examined on pre-contracted tracheal chains of guinea pig by KCl and methacholine in non-incubated tissues and incubated tissues with propranolol. The results suggested that the relaxant effect of essential oil from Carum copticum is mainly due to its fraction 2 (presumably carvacrol) and to a lesser extent fraction 3. The relaxant effects of all volumes of fractions were not significantly different between incubated and non-incubated tissues. As a result, their relaxant effects were not due to β-adrenergic stimulatory effect.³⁷

The bronchodilatory effects of three cumulative volumes of carvacrol (Sigma Chemical Ltd, UK), one of the constituents of Carum copticum, were examined by their relaxant effects on tracheal chains of guinea pigs pre-contracted by KCl and methacholine in two different conditions, non-incubated tissues and incubated tissues with propranolol. There was no significant difference in the relaxant effects of most volumes of carvacrol between non-incubated tissue and incubated tissue with propranolol. The results indicated that carvacrol has a potent relaxant effect on tracheal chains of guinea pigs, which was not due to β₂-adrenergic stimulatory effect.³⁸

The relaxant effects of four cumulative concentrations of aqueous-ethanolic extract of Crocus sativus were examined on guinea-pig tracheal chains. The tracheal chains have been pre-contracted using 60 mM KCl in non-incubated tissues and tissues incubated with 1 mM propranolol. The relaxant effects of most concentrations of extract in incubated tissues with propranolol were significantly lower than those of non-incubated tissues. The results suggested that the relaxant effect of this plant could be due to β₂-adrenoceptor stimulatory effect.³⁹

The relaxant effects of three cumulative concentrations of crocin (Sigma Chemical Co, St Louis, MO, USA), a constituent of Crocus sativus, were examined on pre-contracted tracheal smooth muscle by KCl in non-incubated or incubated with propranolol. There was no significant difference in the relaxant effects of crocin between non-incubated and incubated tissues with propranolol. The results also showed significant difference in EC₅₀ values of crocin, between non-incubated and incubated tissues with propranolol. The higher EC₅₀ value obtained in incubated tissues with propranolol may indicate a component of stimulatory effect of crocin on β2-adrenergceptors.⁴⁰
To evaluate the contribution of the $\beta_2$-adrenergic stimulatory effect of the macerated and aqueous extracts of *Cuminum cyminum*, the effects of four cumulative concentrations of these extracts on guinea pig tracheal chains were examined in the presence of propranolol. In propranolol-incubated tissues, the extracts of *Cuminum cyminum* did not show any significant relaxant effect on guinea pig tracheal chains. Only two last concentrations of macerated extracts showed non-significant relaxant effect on tracheal chains. The relaxant effects of most concentrations of both extracts in incubated tissues with propranolol were significantly lower than those of non-incubated tissues. The results showed a potent relaxant effect of *Cuminum cyminum* which may be due to a stimulatory effect of the plant on $\beta_2$-adrenoceptors.41

The relaxant effects of four cumulative concentrations of hydro-ethanolic extract of *Curcuma longa* were studied on tracheal smooth muscle pre-contracted by methacholine or KCl in non-incubated or incubated with propranolol. In tracheal smooth muscle incubated with propranolol, extract showed significant and concentration dependent relaxant effects. There was no significant difference in the relaxant effects of the *Curcuma longa* extract between non-incubated and incubated tissues with propranolol. The authors suggest that the relaxant effect of the extract was not due to its effect on $\beta$-adrenergic stimulatory effect.42

The relaxant effects of the aqueous extract of *Ferula assafoetida* were examined on tracheal smooth muscle of guinea pig pre-contracted by methacholine in non-incubated and incubated with propranolol. There was no significant difference in the relaxant effects of the extract between non-incubated and incubated tissues with propranolol. The results showed a relaxant effect for the asafetida extract on tracheal smooth muscle, which was not due to $\beta$-adrenoceptors stimulation.25

The relaxant effect of aqueous extract of *Hypoxis hemerocallidea* corm (African potato) was examined on spasmsogen (histamine, carbachol and potassium)-provoked contractions of guinea-pig isolated tracheal smooth muscle preparations. The extract relaxed spasmsogen-induced contractions in a concentration dependent manner. The relaxant effects of the extract were not altered by bath-applied propranolol (3.0 µg/mL), which markedly inhibited or completely abolished the relaxant effects of isoprenaline (0.1-5.0 µg/mL). It is unlikely that the aqueous extract of *Hypoxis hemerocallidea* stimulates the $\beta_2$-adrenoceptors.43

The contribution of $\beta_2$-adrenergic stimulatory effect of macerated and soxhlet extracts of (pulp) of *Liomnia acidissimain* and their relaxant actions has been examined. The effects of these extracts were examined on pre-contracted tracheal chains by 60 mM KCl, 10 μM methacholine in non-incubated condition and propranolol (1 μM) incubated tissues contracted by 10 μM methacholine. The relaxant effects of all concentrations of the macerated and soxhlet extracts on propranolol incubated tissues were significantly higher than those of non-incubated tissues. Since the plant showed a potent relaxant effect which was completely blocked in incubated tissues with propranolol, the inhibitory effect of the plant on $\beta$-adrenoceptors is most probable with these results.44

The relaxant effects of essential oil, aqueous and ethanol extracts of *Pimpinella anisum* were examined on pre-contracted tracheal smooth muscle of the guinea pig by methacholine in two different conditions, non-incubated and incubated with propranolol. There was no significant difference in the relaxant effects of the extract between non-incubated and incubated tissues. The results showed that the relaxant effect of this plant was not due to the stimulatory effect of $\beta_2$-adrenergic receptors.28

The relaxant effects of five cumulative concentrations of boiled and aqueous extracts of *Portulaca oleracea* were examined by their relaxant effects in tracheal chains of guinea pig pre-contracted with KCl and methacholine under two different conditions, non-incubated and incubated tissues with propranolol. The relaxant effects of most concentrations of both extracts from *Portulaca oleracea* obtained in incubated tissues were non-significantly greater than those of non-incubated tissues. These findings showed the absence of $\beta$-adrenergic stimulatory property of the plant extracts.36

The relaxant effects of four cumulative concentrations of Ethanolic extract and essential oils of *Rosa damascena* on tracheal chains of guinea pigs were examined by 60 mM KCl and 10 μM methacholine in two different conditions, non-incubated and incubated tissues with 1 μM propranolol. In incubated tissues with propranolol, Ethanolic extract and essential oil of *Rosa damascena* did not show any significant relaxant effect compared to the effect of saline. The effects of most concentrations of ethanolic extract and essential
oils in incubated tissues with propranolol were statistically lower than in those of non-incubated tissues. The results showed that the most probable mechanism responsible for the relaxant effect of *Rosa damascena* was a stimulatory effect on $\beta_2$-adrenoceptors.\(^{45}\)

The relaxant properties of six cumulative concentrations of hydro-ethanolic extract of *Satureja hortensis* on tracheal chains of guinea pigs were examined. Tracheal chains were contracted by 10 $\mu$M methacholine or 60 mM KCl and relaxant effect of the plant in two different conditions (non-incubated and incubated tissues with 1 $\mu$M propranolol) were evaluated. In incubated tissues with propranolol, *Satureja hortensis* did not show any significant relaxant effect compared to the effect of saline. The relaxant effects of most concentrations of extract in non-incubated tissues were statistically greater than those of incubated tissues. These findings suggested a probable $\beta_2$-adrenergic stimulatory property of the plant extract that may contribute to its relaxant effect on tracheal chins of guinea pig.\(^{46}\)

The relaxant effects of macerated and aqueous extracts of *Thymus vulgaris* were examined on pre-contracted tracheal chains of guinea-pig (60 mM KCl and 10 $\mu$M methacholine) in non-incubated tissues and incubated tissues with 1 $\mu$M propranolol. In incubated tissues with propranolol, the extracts of *Thymus vulgaris* did not show any significant relaxant effect compared to the effect of saline. The relaxant effects of most concentrations of both extracts in non-incubated tissues were statistically greater than those of incubated tissues with propranolol. The results suggested that the relaxant effect of this plant could be due to $\beta_2$-adrenoceptor stimulatory effect.\(^{47}\)

In Table 1, the stimulatory effect of the extracts and constituents of medicinal plants on $\beta_2$-adrenoceptors in tracheal smooth muscle by examining their relaxant effect on non-incubated and incubated tissues with a competitive $\beta_2$-antagonist are summarized.

### Effects of Medicinal Plants on $\beta_2$-Adrenoceptors Incubated TSM with Propranolol on Concentration-Response Curve to Histamine and Methacholine

The stimulatory effect of three concentrations of *Achillea millefolium* aqueous-ethanolic extract on $\beta_2$-adrenoceptors in tracheal smooth muscle was tested by performing cumulative concentration-response curves of methacholine induced contraction in non-incubated and incubated tissues with propranolol. The EC\(_{50}\) obtained in the presence of various concentrations of the extract were significantly in incubated tissues compared to non-incubated tissues. These results suggested the stimulatory effect of this plant on $\beta_2$-adreno receptors.\(^{48}\)

The stimulatory effect of essential oil and aqueous extract of *Bunium persicum* on $\beta_2$-adrenoceptors in tracheal smooth muscle was tested by performing cumulative concentration-response curves of histamine induced contraction in non-incubated and incubated tissues with propranolol. The results demonstrated that the slope of histamine-response curves obtained in the presence of essential oil and aqueous extract, and maximum response in the presence of aqueous extract as well as EC\(_{50}\) obtained the presence of essential oil in incubated tissues were significantly higher than those of non-incubated tissues. These findings suggested a stimulatory effect of essential oil and aqueous extract of *Bunium persicum* on $\beta_2$-adrenergic receptors.\(^{49}\)

To evaluate the contribution of the $\beta_2$-adrenergic stimulatory effects of the essential oil and ethanol extract of *Carum copticum*, the effects of these extracts were examined by performing the cumulative log concentration-response curves of histamine induced contraction on guinea pig tracheal chains in non-incubated and incubated tissues with propranolol. The results indicated that in the presence of essential oil, only in incubated tissues with propranolol histamine-response achieved the maximum response in the presence of ethanol extract which suggest a $\beta_2$-adrenergic stimulatory effect of essential oil and ethanol extract of this plant.\(^{50}\)

The effects of three concentrations of safranal (Sigma Chemical Co, St Louis, MO, USA), one constituent of *Crocus sativus* on tracheal smooth muscle of guinea pigs were examined by performing cumulative concentration-response curves of histamine induced contraction in two different conditions, non-incubated tissues and incubated tissues with propranolol. The maximum responses and the slope of histamine-response curves obtained in the presence of two higher concentrations of safranal and EC\(_{50}\) obtained in the presence of all concentrations of safranal were significantly higher in incubated tissues compared to non-incubated tissues. These results suggested the stimulatory effect of safranal on $\beta_2$-adreno receptors.\(^{51}\)

Relaxant effect examination on KCl or methacholine induced contraction in non-incubated and incubated tissues with propranolol.

Abbreviations: Ext.: Extract, Cons.: Constituents, Conc.: Concentration AE.: Aqueous extract, BE: Boiled extract, EE: Ethanolic extract, ME.: Macerated extract, EO: Essential oil, HEE: Hydro-ethanolic extract, +: Stimulatory effect, −: Non-stimulatory effect

The stimulatory effect of three concentrations of *Crocus sativus* hydro-ethanolic extract on $\beta_2$-adrenoceptors in tracheal smooth muscle was tested by performing cumulative concentration-response curves of histamine induced contraction in non-incubated and incubated tissues with propranolol. The results showed the maximum responses, the slope of histamine-response curves and EC$_{50}$ obtained in the presence of two higher concentrations of the extract were significantly lower than in non-incubated tissues.
compared to incubated tissues. These findings suggested probable $\beta_2$-adrenergic stimulatory effect of this extract.\textsuperscript{52}

The effect of macerated extract of \textit{Nigella sativa} was tested by performing the cumulative log concentration-response curves of histamine induced contraction of isolated guinea pig tracheal chains with non-incubated and incubated tissues with propranolol. The results showed non-significant decrease in maximum response to histamine and the slope of the curves, between non-incubated and incubated tissues with propranolol which suggested probable $\beta_2$-adrenergic inhibitory effect of this extract.\textsuperscript{53}

Cumulative concentration-response curves of methacholine induced contraction in non-incubated and incubated tracheal smooth muscles with propranolol in the presence of three concentrations of \textit{Portulaca oleracea} aqueous-ethanolic extract showed no significant difference in the maximum response, EC$_{50}$ and the slope of methacholine-response curves between in non-incubated and incubated tissues. These results showed the absence of stimulatory effect of this plant on $\beta_2$-adrenergoreceptors.\textsuperscript{53}

Cumulative concentration-response curves of histamine induced contraction in non-incubated and incubated tissues with propranolol in the presence of three concentrations of \textit{Zataria multiflora} hydro-ethanolic extract were also performed. The results showed that the values of CR-1 obtained in the presence of two lower concentrations of the extract were significantly higher than in non-incubated tissues compared to incubated tissues which suggested a stimulatory effect of the plant on $\beta_2$-adrenergic receptors.\textsuperscript{54,55}

The effect of \textit{Zataria multiflora} hydro-ethanolic extract was tested by performing the cumulative log concentration-response curves of methacholine induced contraction of isolated guinea pig tracheal smooth muscle with non-incubated and incubated tissues with propranolol. The maximum response obtained in the presence of all concentrations of the extract, and the slope of methacholine-response curves in the presence of two higher concentrations of the extract as well as EC$_{50}$ obtained in the presence of high concentration extract in incubated tissues were significantly higher than non-incubated tissues. These findings suggested a stimulatory effect of this plant on $\beta_2$-adrenergic receptors.\textsuperscript{56}

The effects of three concentrations of carvacrol (Sigma Chemical Ltd UK), one constituent of \textit{Zataria multiflora} on tracheal smooth muscle of guinea pigs were examined by performing cumulative concentration-response curves of methacholine induced contraction in non-incubated and incubated tissues with propranolol. The results showed that the maximum responses and the values of CR-1 obtained in the presence of all concentrations of carvacrol and EC$_{50}$ obtained in the presence of two higher concentrations of carvacrol were significantly higher in incubated tissues compared to non-incubated tissues. These findings suggested a probable $\beta_2$-adrenergic stimulatory effect of carvacrol.\textsuperscript{57}

The stimulatory effect of the extracts and constituents of medicinal plants on $\beta_2$-adrenoceptors in tracheal smooth muscle by performing concentration-response curve to histamine and methacholine in non-incubated and incubated tissues with propranolol are summarized in Table 2.

### Effects of Medicinal Plants on $\beta_2$-Adrenoceptors Using Concentration-Response Curves to a $\beta_2$-Adrenergic Agonist

As mentioned, the stimulation of $\beta_2$-adrenergic receptors is one of the major mechanisms involving in the relaxant effect of medicinal plants on tracheal smooth muscle.\textsuperscript{58} A well-known method for evaluation of the plants stimulatory effects on $\beta_2$-adrenoceptors in airway smooth muscles is performing the concentration-response curves to $\beta_2$-adrenoceptor agonist such as isoprenaline in the presence or absence of medicinal plants, which is more scientific method for this purpose. Leftward shift of $\beta_2$-agonist concentration-response curve indicates a stimulatory effect of the plant on $\beta_2$-adrenoceptors. Several studies were used this method to evaluated stimulatory effects of medicinal plants on $\beta_2$-adrenergic receptors.

The possible mechanism of the relaxant effect of three concentrations of \textit{Achillea millefolium} hydro-ethanolic extract on tracheal smooth muscles was determined by performing concentration-response curves to isoprenaline in methacholine-contracted tracheal smooth muscle in the presence of the extract, propranolol and saline. Two high concentrations of extract led to leftward shifts in isoprenaline curves and also reduction of EC$_{50}$ isoprenaline compared to saline while the isoprenaline curve showed a clear rightward shift in the presence of propranolol.
The Stimulatory Effects of Medicinal Plants on β2-adrenoceptors

Table 2. The stimulatory effect of the extracts and constituents of medicinal plants on β2-adrenoceptors in tracheal smooth muscle by performing concentration-response curve to histamine and methacholine in non-incubated and incubated tissues with propranolol

Abbreviations: Ext: Extract, Cons.: Constituents, Conc.: Concentration AE: Aqueous extract, EE: Ethanolic extract, ME: Macerated extract, EO: Essential oil, HEE: Hydro-ethanolic extract, EC50: Effective concentration causing 50% of maximum response, CR-1: concentration ratio minus one, +: Stimulatory effect, −: non-stimulatory effect

Therefore, the extract of *Achillea millefolium* showed small stimulatory effect on β2-adrenergic receptors. In a study, the stimulatory effect of macerated, aqueous and ethanolic extract, and essential oil of *Carum copticum* on β2-adrenoreceptors of guinea pig tracheal smooth muscle was also examined. Performing of concentration-response curves of isoprenaline in the presence of extracts, essential oil, saline and propranolol indicated that the only ethanol extract of *Carum copticum* led to leftward shifts in isoprenaline curves. Therefore, ethanolic extract of *Carum copticum* showed a clear stimulatory effect on β2-adrenergic receptors. In a clinical study, the bronchodilatory effect of 0.125 and 0.25 mL/kg of 10 g% boiled extract of *Carum copticum* in airways of asthmatic patients was also shown. According to previous studies, various mechanisms for the bronchodilator effect of this plant have been proposed. However, the possible mechanism for the bronchodilatory effect of this plant on the small airways is stimulation of β2-adrenoreceptors due to the high density of these
receptors in small airways. The stimulatory effect of hydro-ethanolic extract of Crocus sativus and one of its constituents, safranal, on β₂-adrenoceptors in tracheal smooth muscle was tested by performing cumulative concentration-response curves of isoprenaline-induced relaxation on pre-contracted smooth muscle. The results demonstrated leftward shifts in isoprenaline curves in the presence of the extract, safranal but rightward shift of isoprenaline curve in the presence of propranolol. In addition, as decrease in EC₅₀ isoprenaline was also observed in the presence of Crocus sativus extract and safranal. These results pharmacologically indicate the stimulatory effect for the plant extract and safranal on β₂-adrenoceptors.

Ephedrine is one of the constituents of Ephedra sinica (also known as Chinese ephedra). The relaxant effect of ephedrine on the tracheal smooth muscles of guinea pigs through β₂-adrenoceptors stimulating mechanism was investigated. For this purpose, concentration-response curves for isoprenaline in tracheal tissue were drawn. These findings demonstrated a rightward shift of the concentration-response curves for isoprenaline in the presence of the ephedrine, which indicates the small inhibitory effect of ephedrine on β₂-adrenoceptors and suggests that other mechanisms may involve in the relaxant effect of ephedrine.

Similarity to investigate the possible mechanism of the relaxant effect of optical isomers of ephedrine in guinea pig tracheal smooth muscle, the l-ephedrine concentration-response curve in the presence of propranolol was performed. The results showed a rightward shift of the l-ephedrine concentration-response curve for propranolol. Therefore, these findings may suggest that l-ephedrine-induced relaxation of the guinea pig trachea is mediated by β₂-adrenoceptors.

Boskabady et al demonstrated the stimulatory effect of the aqueous and macerated extracts of Nigella sativa on β₂-adrenoceptors tracheal smooth muscle of guinea-pigs. Concentration-response curves to isoprenaline in tracheal smooth muscle indicated leftward shifts in the presence of the both extracts. The results showed a clear stimulatory effect on β₂-adrenoceptors for the aqueous extract of this plant while macerated extracts of Nigella sativa indicate a possible stimulatory effect on β₂-adrenoceptors.

Another study was shown that hydro-ethanolic extract of Portulaca oleracea affects beta-adrenoceptors of guinea pig tracheal smooth muscle. For this purpose, concentration-response curve to isoprenaline was obtained in the presence of three concentrations of hydro-ethanolic extract, propranolol, and saline. The results indicated leftward shift of concentration-response curves to isoprenaline in the presence of the extract, while the curve of propranolol showed a rightward shift compared to isoprenaline curves. EC₅₀ isoprenaline in the presence of the extract was also decreased. These results showed a stimulatory effect of this plant on β₂-adrenoceptors.

Zataria multiflora Boiss and its constituent, carvacrol (Fluka, Italy, Catalogue no. C4915, purity 75%), also showed the stimulatory effects on β₂-adrenoceptors of the guinea pig trachea. To examine the stimulatory effect of β₂-adrenoceptors, cumulative log concentration-response curves to isoprenaline in the presence of extracts, carvacrol and propranolol were performed. The results showed the leftward shifts in isoprenaline curves in the presence of the hydro-ethanolic extract (0.5, 1, and 2μg/mL) and carvacrol as well as decrease of EC₅₀ isoprenaline value while, curve of propranolol showed a rightward shift. Therefore, the results suggest the stimulatory effect for the plant extract and carvacrol on β₂-adrenoceptors. Moreover, the effect of three concentrations (0.05, 0.1 and 0.2 mg/mL) of Zataria multiflora hydro-ethanolic extract on β₂-adrenoceptors in tracheal smooth muscles were also evaluated by similar method as described above. The results showed the stimulatory effect of this plant on β₂-adrenoceptors of the tracheal smooth muscles of guinea pigs. In another study, the stimulatory effect of Zataria multiflora on β₂-adrenergic receptors on guinea pig tracheal smooth muscle was also suggested.

The stimulatory effect of the extracts and constituents of medicinal plants on β₂-adrenoceptors in tracheal smooth muscle by performing cumulative log concentration-response curves to isoprenaline are summarized in Table 3.

Cumulative log concentration-response curve (CLCRC) of Isop. of guinea pig tracheal chain was performed in presence of the various extracts of medicinal plants and constituents, propranolol and saline. Abbreviations: Ext.: Extract, Cons.: Constituents, Conc.: Concentration, AE: Aqueous extract, EE: Ethanolic extract, ME: Macerated extract, EO: Essential oil, HEE: Hydro-ethanolic extract, Isop: Isoprenaline, EC50: Effective concentration causing 50% of maximum response. +: Stimulatory effect, ±: Small stimulatory effect.

Figure 5. Current knowledge about the effect of natural products (mainly medicinal plants and their constituents) on respiratory disease and suggested further studies.
CONCLUSION

Beta₂-adrenoceptors stimulatory drugs are one of the most important bronchodilatory drugs which used to relieve bronchoconstriction in pulmonary obstructive disease mainly asthma. The knowledge regarding the use of medicinal plants in obstructive pulmonary disease has been poor yet. Therefore, the stimulatory effect of medicinal plants on β₂-adrenoceptors which could be pointed to use of medicinal plant with this property as bronchodilatory drugs were reviewed. This review showed the relaxant effect of medicinal plants, their fractions and constituents on tracheal smooth muscle, which indicated their bronchodilatory effect by β₂-adrenoceptors stimulatory mechanism. As a result, the tracheal relaxant effect of Achillea millefolium, Carum copticom, Carumcarvi, Crocus sativus, Cuminum cyminum, Ephedra sinica, Liomnia acidissima, Nigella sativa, Portulaca oleraceae, Rosa damascena, Satureja hortensis, Thymus vulgaris, and Zataria multiflora, some of their fractions and constituents may be mediated via β₂-adrenoceptors stimulation.

Therefore, the extracts and essential oil of the above medicinal plant, their fractions and constituents would be of therapeutic potential on obstructive pulmonary diseases as bronchodilator or relieving drugs by this mechanism. However, further clinical and experimental studies were required to demonstrate the clinical applications of the mentioned medicinal plants, their fractions and constituents on pulmonary obstructive diseases such as asthma more clearly.
